Inverse Problem in Optical Diffusion Tomography.

IV. Nonlinear Inversion Formulas

Abstract

In this paper we continue our study of the inverse scattering problem for diffuse light. In contrast to our earlier work in which we considered the linear inverse problem, here we consider the nonlinear problem. We obtain a solution to this problem in the form of a functional series expansion. The first term in this expansion is the pseudoinverse of the linearized forward scattering operator and leads to the linear inversion formulas that we have reported previously. The higher order terms represent nonlinear corrections to this result. We illustrate our results with computer simulations in model systems.

1. Introduction

This paper is the fourth in a series devoted to the inverse scattering problem (ISP) which arises in the context of tomographic imaging with diffuse light. In parts I–III of the series\textsuperscript{1–3} we developed the scattering theory of diffusing waves in inhomogeneous media, established conditions under which the existence and uniqueness of solutions to the linearized inverse problem are guaranteed, constructed the singular value decomposition (SVD) of the forward scattering operator under conditions of weak scattering, and used these results to obtain
explicit inversion formulas for the case of the \textit{linearized} ISP. The purpose of this paper is to extend these results to the \textit{nonlinear} case.

We begin by recalling the relevant mathematical formalism from Parts I–III. We assume that the energy density $u(r, t)$ of diffuse light in an inhomogeneous medium obeys the diffusion equation

$$\frac{\partial u(r, t)}{\partial t} = \nabla \cdot \left[ D(r) \nabla u(r, t) \right] - \alpha(r) u(r, t) + S(r, t) ,$$

where $\alpha(r)$ and $D(r)$ are the position-dependent absorption and diffusion coefficients, and $S(r, t)$ is the power density of the source. We further assume that the source is harmonically modulated with angular frequency $\omega$. In addition to (1), the energy density must satisfy boundary conditions on the surface of the medium (or at infinity in the case of free boundaries) of the general form

$$u + \ell \hat{n} \cdot \nabla u = 0 ,$$

where $\ell$ is the extrapolation length and $\hat{n}$ is an outward pointing normal. Note that when $\ell = 0$ we obtain purely absorbing boundaries and when $\ell \to \infty$ purely reflecting boundaries.

As shown in Parts I and II, the Green’s function $G(r_1, r_2)$ for the frequency-domain diffusion equation obeys the integral equation

$$G(r_1, r_2) = G_0(r_1, r_2) - \int d^3r G_0(r_1, r) V(r) G(r, r_2) ,$$

where $G_0$ is the Green’s function for a homogeneous medium with absorption $\alpha_0$ and diffusion constant $D_0$. We have also introduced the notation

$$V(r) \equiv \delta \alpha(r) - \nabla \cdot \delta D(r) \nabla ,$$

where $\delta \alpha(r) = \alpha(r) - \alpha_0$ and $\delta D(r) = D(r) - D_0$. The unperturbed Green’s function $G_0(r, r')$ obeys the boundary condition (2) and satisfies

$$\left( \nabla^2 - k^2 \right) G_0(r, r') = -\frac{1}{D_0} \delta(r - r') ,$$
where the diffuse wave number $k$ is given by

$$k^2 = \frac{\alpha_0 - i\omega}{D_0}.$$  

(6)

The Green’s function may be directly related to the intensity measured by a point detector when the medium is illuminated by a point source. It can be shown that the change in the intensity of transmitted light (at the modulation frequency $\omega$) due to spatial fluctuations in $\alpha(r)$ and $D(r)$ is given by the integral equation

$$\phi(r_1, r_2) = \beta \int G_0(r_1, r)V(r)G(r, r_2)d^3r.$$  

(7)

Here the data function $\phi(r_1, r_2)$ is proportional to the change in intensity relative to a reference medium with absorption $\alpha_0$ and diffusion constant $D_0$, $r_1$ and $r_2$ denote the coordinates of the source and detector, and

$$\beta = \begin{cases} 
1 & \text{for free boundaries} \\
(1 + \ell^*/\ell)^2 & \text{for boundary conditions of type (2)}
\end{cases}$$  

with $\ell^* = 3D_0/c$.

The forward problem in diffusion tomography is defined as the problem of computing the data function $\phi$ from the scattering potential $\eta = (\delta\alpha, \delta D)$. More precisely, the integral equation (7) may be regarded as defining a nonlinear operator $K$ from the Hilbert space of scattering potentials $\mathcal{H}_1$ into the Hilbert space of scattering data $\mathcal{H}_2$. The fact that $K$ is nonlinear may be understood by examining the perturbation expansion for $\phi$ in powers of $V$. Using the series expansion for the Green’s function $G$, which can be obtained by iterating the integral equation (3), and the definition of the data function (7) we obtain the required expansion:

$$\phi(r_1, r_2) = \beta \int d^3r G_0(r_1, r)V(r)G_0(r, r_2)$$

$$+ \beta \int d^3r d^3r'G_0(r_1, r)V(r)G_0(r, r')V(r')G_0(r', r_2) + \cdots$$  

(9)

If only the first term in the series is retained we refer to this as the weak-scattering approximation.
The inverse problem in diffusion tomography consists of recovering $\eta$ from measurements of $\phi$. The standard numerical approach to this nonlinear problem is to employ a functional Newton’s method\(^5\). This results in an iterative algorithm of the form

$$\eta_{n+1} = \eta_n + M_n^+ (\phi - K[\eta_n]) , \quad n = 1, 2, \ldots ,$$  \hspace{1cm} (10)

where $M_n^+$ denotes the pseudoinverse of the functional derivative

$$M_n = \frac{\delta K}{\delta \eta} \bigg|_{\eta = \eta_n} .$$  \hspace{1cm} (11)

The Newton-Kantorovich method is a variant of Newton’s method in which the functional derivative $M_n^+$ is replaced by $M_1^+$ for all $n$. In general, this leads to an algorithm with slower convergence than Newton’s method. However, newton-kantorovich method is of interest since it is possible to obtain an analytic expression for $M_1^+$ when $\eta_1 \equiv 0$.

In this paper we consider an alternative to the use of Newton’s method. In particular, we construct a formally exact analytic solution to the nonlinear ISP. This solution, which we refer to as the inverse scattering series, has the form of a functional series expansion for $\eta$ in powers of the data function $\phi$. The first term in the expansion corresponds to the pseudoinverse solution to the linearized inverse problem. The higher order terms may be interpreted as nonlinear corrections to the SVD inversion formulas reported in part III. We will also show that summing the inverse scattering series to all orders is equivalent to solving the ISP by the Newton-Kantorovich method.

Series solutions to several nonlinear ISPs have been reported in the literature. These include quantum mechanical and acoustic inverse backscattering\(^6,7\) and nonlinear travel-time tomography\(^8,9\). The formal inversion of functional expansions such as the Volterra series is also well known in nonlinear control theory. It is important to note that although the algebraic structure of the inverse scattering series in diffusion tomography is similar to that in quantum mechanics or acoustics, its analytic structure is quite different. This reflects the underlying physical difference between the short-range propagation of diffusive waves in diffusion tomography and the long-range propagation of waves in quantum mechanics or acoustics.
The reminder of this paper is organized as follows. In Section 2 we derive the inverse scattering series for diffusion tomography in its most general form, independent of geometry and the type of boundary conditions. In Section 3 we consider the inverse problem in the biplanar geometry. Finally, Section 4 describes numerical results for the nonlinear reconstruction of a spherical inhomogeneity in the biplanar geometry. Two appendices present some mathematical properties of the inverse scattering series and the derivation of the data function for a spherical inhomogeneity in the biplanar geometry with free boundaries.

2. Inverse Problem

In this section we present the construction of the inverse scattering series for diffusion tomography. We then describe the connection to the Newton-Kantorovich method.

A. Inverse scattering series

The scattering series (9) can be rewritten in the form

$$\phi(r_1, r_2) = \int d^3r K^i_1(r_1, r_2; r) \eta_i(r) + \int d^3r d^3r' K^ij_2(r_1, r_2; r, r') \eta_i(r) \eta_j(r') + \cdots, \quad (12)$$

where

$$\eta(r) = \left( \begin{array}{c} \eta_1(r) \\ \eta_2(r) \end{array} \right) = \left( \begin{array}{c} \delta \alpha(r) \\ \delta D(r) \end{array} \right), \quad (13)$$

the action of the operator $V$ has been taken into account and summation over repeated indices is implied with $i, j = 1, 2$. The components of the operators $K_1$ and $K_2$ are given by

$$K^1_{11}(r_1, r_2; r) = \beta G_0(r_1, r) G_0(r, r_2), \quad (14)$$

$$K^2_{11}(r_1, r_2; r) = \beta \nabla_r G_0(r_1, r) \cdot \nabla_r G_0(r, r_2), \quad (15)$$

$$K^{12}_{21}(r_1, r_2; r, r') = -\beta G_0(r_1, r) G_0(r, r') G_0(r', r_2), \quad (16)$$

$$K^{22}_{21}(r_1, r_2; r, r') = -\beta \nabla_r G_0(r_1, r) \nabla_r G_0(r, r') \cdot \nabla_r' G_0(r', r_2), \quad (17)$$

$$K^{21}_{21}(r_1, r_2; r, r') = -\beta \nabla_r G_0(r_1, r) \cdot \nabla_r G_0(r, r') G_0(r', r_2), \quad (18)$$
\[ K_{22}^{22}(\mathbf{r}_1, \mathbf{r}_2; \mathbf{r}, \mathbf{r}') = -\beta \nabla_\mathbf{r} G_0(\mathbf{r}_1, \mathbf{r}) \cdot \nabla_\mathbf{r} \left[ \nabla_\mathbf{r}' G_0(\mathbf{r}, \mathbf{r}') \cdot \nabla_\mathbf{r}' G_0(\mathbf{r}', \mathbf{r}_2) \right] . \] (19)

The components of \( K_n \) are given by

\[ K_{i_1...i_n}^n(\mathbf{r}_1, \mathbf{r}_2; \mathbf{R}_1, \ldots, \mathbf{R}_n) = (-1)^n \sum_{\alpha_1, \ldots, \alpha_n} \frac{\partial^{i_{1+}} G_0(\mathbf{r}_1, \mathbf{R}_1)}{\partial R_{\alpha_{i_1}}^{\alpha_1 - 1}} \frac{\partial^{i_{2+}} G_0(\mathbf{R}_1, \mathbf{R}_2)}{\partial R_{\alpha_{i_2}}^{\alpha_2 - 1}} \times \ldots \times \frac{\partial^{i_{n+}} G_0(\mathbf{R}_{n-1}, \mathbf{R}_n)}{\partial R_{\alpha_{i_n}}^{\alpha_n - 1}} \frac{\partial^{i_n-} G_0(\mathbf{R}_n, \mathbf{r}_2)}{\partial R_{\alpha_{i_n}}^{\alpha_n - 1}}, \] (20)

where \( \alpha, \ldots, \alpha_n \) label Cartesian components of the vectors \( \mathbf{R}_1, \ldots, \mathbf{R}_n \) and no summation should be performed over indexes which are not explicitly present in the sum (i.e., for \( i_k = 1 \)).

Observe that (12) is a functional power series expansion each term of which is multilinear in \( \eta \). Thus we can expand \( \phi \) in tensor powers of \( \eta \)

\[ \phi = K_1 \eta + K_2 \eta \otimes \eta + \cdots . \] (21)

Here \( K_1 \) is a linear operator which maps the Hilbert space \( \mathcal{H}_1 \) into the Hilbert space \( \mathcal{H}_2 \) and \( K_2 \) may be interpreted as a tensor operator which maps \( \mathcal{H}_1 \otimes \mathcal{H}_1 \) into \( \mathcal{H}_2 \). Eqs. (9) and (21) are analogous to the Born series in quantum scattering theory. Alternative perturbation expansions such as the Rytov series may also be considered.

If the spatial fluctuations in \( \alpha \) and \( D \) are sufficiently small, the series (21) may be truncated after its first term. This results in an effective linearization of the forward scattering problem with \( \phi = K_1 \eta \). The corresponding linear ISP has the solution \( \eta = K_1^+ \phi \), where \( K_1^+ \) denotes the pseudoinverse of \( K_1 \). To construct the solution to the nonlinear ISP we act on (21) with the pseudoinverse operator \( K_1^+ \) and use the identity \( K_1^+ K_1 = I_{\mathcal{H}_1} \). We thus obtain

\[ \eta = K_1^+ \phi - K_1^+ K_2 \eta \otimes \eta + \cdots . \] (22)

Next, by iterating this result we find that

\[ \eta = K_1^+ \phi - K_1^+ K_2 K_1^+ \otimes K_1^+ \phi \otimes \phi + \cdots , \] (23)

which is a functional expansion for \( \eta \) in tensor powers of \( \phi \). We will refer to (23) as the inverse scattering series for diffusion tomography.
Several comments on the above result are necessary. First, (23) provides a formally exact solution to the inverse problem in diffusion tomography. It may be viewed as a nonlinear inversion formula whose first term coincides with the pseudoinverse solution to the linearized ISP. The higher order terms represent systematically improvable nonlinear corrections which, in principle, can be computed to arbitrarily high order. Thus, it is only necessary to solve the linear ISP in order to formally solve the nonlinear ISP. Second, (23) may also be obtained by formal inversion of the functional power series (9). This results in an explicit formula for the coefficient $\mathcal{K}_n$ of the the $n$th term in (23):

$$
\mathcal{K}_n = - \left( \sum_{p=1}^{n-1} \mathcal{K}_p \sum_{i_1 + \cdots + i_p = n} K_{i_1} \otimes \cdots \otimes K_{i_p} \right) K_1 \otimes \cdots \otimes K_1 ,
$$

where $K_1 = K_1^+$. See Appendix A. Third, it may be seen that the coefficients of all the higher order terms in (23) have $K_1^+$ as a prefactor. As a result, to any finite order, the spatial resolution of images reconstructed using the nonlinear theory can never exceed the resolution of images reconstructed by linear means alone. Fourth, the short-range propagation of diffusive waves implies that the forward scattering problem in diffusion tomography is weakly nonlinear. This is precisely the condition under which the inverse scattering series may be expected to exhibit fast convergence. Note that a detailed analysis of the convergence of the inverse scattering series is beyond the scope of this paper. Finally, the approach to the ISP based on (23) differs from Newton-type methods. This follows from the fact that such methods require the forward problem to be solved for each iteration.

\textbf{B. Relation to Newton’s method}

We will now show that summing the inverse scattering series to all orders is equivalent to the Newton-Kantorovich method. To see this we rearrange (22) as follows:

$$
\eta = K_1^+ (\phi - K_2 \eta \otimes \eta + \cdots )
$$

$$
= K_1^+ (\phi - (K[\eta] - K_1 \eta))
$$

$$
= \eta + K_1^+ (\phi - K[\eta])
$$

7
\[ \equiv T[\eta] \] , \hspace{1cm} (28)

where in (26) we have used the functional expansion for the forward scattering operator \( K \).

Eq. (28) implies that the ISP may be reduced to the problem of finding the fixed point of the nonlinear transformation \( T \). The fixed point may be obtained by iteration of \( \eta_{n+1} = T[\eta_n] \), or more explicitly

\[ \eta_{n+1} = \eta_n + K_1^+ (\phi - K[\eta_n]) \] , \hspace{1cm} n = 1, 2, \ldots . \hspace{1cm} (29)

Eq. (29) coincides with the Newton-Kantorovich method if the functional derivative \( M_1 = K_1 \). Evidently, this condition is obeyed if the initial condition in the Newton’s method iteration (10) is chosen to be \( \eta_1 = 0 \), that is if the initial condition corresponds to a homogeneous medium.

3. Nonlinear Inversion in the Planar Geometry

The inverse scattering series was developed in a form which is independent of geometry. We now specialize to the case of the planar geometry. Other cases including the cylindrical and spherical geometries may also be considered.

A. Inversion formulas

In the planar geometry measurements are taken on two parallel planes. Sources are taken to be located on the \( z = 0 \) plane and detectors on the plane \( z = L \). The medium to be imaged lies between the planes in the region \( 0 < z < L \). In this geometry, the unperturbed Green’s function is given by the plane-wave decomposition

\[
G_0(\mathbf{r}, \mathbf{r}') = \int \frac{d^2 q}{(2\pi)^2} g(q; z, z') \exp[i \mathbf{q} \cdot (\mathbf{\rho} - \mathbf{\rho}')],
\]

where we have used the notation \( \mathbf{r} = (\mathbf{\rho}, z) \). In the case of free boundaries, the function \( g(q; z, z') \) is given by\(^1\)
\[ g(q; z, z') = \frac{\exp \left[ -Q(q) |z - z'| \right]}{2Q(q)D_0} \]  

and in the case of boundary conditions of the type (2) by \(^2\)

\[ g(q; z, z') = \frac{\ell}{D_0 \sinh (Q(q)L) + 2Q(q)\ell \cosh (Q(q)L)} \sinh (Q(q)L) , \]

where \[ Q(q) \equiv (q^2 + k^2)^{1/2} \]

and we have assumed that either \( r \) or \( r' \) lies on one of the measurement planes.

We will find it advantageous to rewrite the inverse scattering series (23) in the form

\[ \eta = \eta^{(1)} + \eta^{(2)} + \cdots \]  
\[ \eta^{(1)} = K_1^+ \phi \]  
\[ \eta^{(2)} = K_1^+ K_2 \eta^{(1)} \otimes \eta^{(1)} , \]

where \( \eta^{(1)} \) is the solution to the linearized ISP and \( \eta^{(2)} \) is the first nonlinear correction. In the planar geometry, since the measurement planes have translational symmetry, it is natural to express (35) and (36) in the Fourier basis of two-dimensional plane waves. In this representation (35) and (36) become

\[ \eta^{(1)}(r) = \int d^2q_1 d^2q_2 K_1^+(r; q_1, q_2) \phi(q_1, q_2) \]  
\[ \eta^{(2)}(r) = \int d^2q_1 d^2q_2 \int d^3 r' d^3 r'' K_1^+(r; q_1, q_2) K_2(q_1, q_2; r', r'') \eta^{(1)}(r') \eta^{(1)}(r'') . \]

Here

\[ \phi(q_1, q_2) = \int d^2 \rho_1 d^2 \rho_2 \exp \left[ i (q_1 \cdot \rho_1 + q_2 \cdot \rho_2) \right] \phi(\rho_1, z_1, \rho_2, z_2) , \]  
\[ K(q_1, q_2; \cdot) = \int d^2 \rho_1 d^2 \rho_2 \exp \left[ i (q_1 \cdot \rho_1 + q_2 \cdot \rho_2) \right] K(\rho_1, z_1, \rho_2, z_2; \cdot) . \]

Note that according to (37) and (38), once \( K_1^+(r; q_1, q_2) \) is determined the inverse problem is solved, in principle.
B. Singular value decomposition of $K_1^+$

The SVD of the pseudoinverse operator $K_1^+$ is given by

$$K_1^+(\mathbf{r}; \mathbf{q}_1, \mathbf{q}_2) = \int \frac{1}{\sigma} f_{\sigma}(\mathbf{r}) g_{\sigma}^*(\mathbf{q}_1, \mathbf{q}_2) d\sigma ,$$  \hspace{1cm} (41)

where $\sigma$ is the singular value associated with the singular functions $f_{\sigma}$ and $g_{\sigma}$. The singular functions are eigenfunctions with eigenvalues $\sigma_2$ of the positive self-adjoint operators $K_1^* K_1$ and $K_1 K_1^*$:

$$K_1^* K_1 f_{\sigma} = \sigma^2 f_{\sigma} ,$$ \hspace{1cm} (42)

$$K_1 K_1^* g_{\sigma} = \sigma^2 g_{\sigma} .$$ \hspace{1cm} (43)

In addition, the singular functions are related by

$$K_1 f_{\sigma} = \sigma g_{\sigma} ,$$ \hspace{1cm} (44)

$$K_1^* g_{\sigma} = \sigma f_{\sigma} .$$ \hspace{1cm} (45)

To proceed further, we require an explicit expression for $K_1(\mathbf{q}_1, \mathbf{q}_2; \mathbf{r})$. This is obtained by using the definitions of $G_0$ from Eq. (30) and $K_1$ from Eqs. (14,15) to carry out the Fourier transformation in Eq. (40):

$$K_1(\mathbf{q}_1, \mathbf{q}_2; \mathbf{r}) = \kappa(\mathbf{q}_1, \mathbf{q}_2; z) \exp \left[ \mathbf{i} \cdot (\mathbf{q}_1 + \mathbf{q}_2) \cdot \mathbf{r} \right] ,$$ \hspace{1cm} (46)

where the components of $\kappa$ are given by

$$\kappa_1(\mathbf{q}_1, \mathbf{q}_2; z) = \beta g(\mathbf{q}_1; z_1, z) g(\mathbf{q}_2; z, z_2) ,$$ \hspace{1cm} (47)

$$\kappa_1(\mathbf{q}_1, \mathbf{q}_2; z) = \beta \left( \frac{\partial g(\mathbf{q}_1; z_1, z)}{\partial z} \frac{\partial g(\mathbf{q}_2; z, z_2)}{\partial z} - \mathbf{q}_1 \cdot \mathbf{q}_2 g(\mathbf{q}_1; z_1, z) g(\mathbf{q}_2; z, z_2) \right) .$$ \hspace{1cm} (48)

Using (46), we find that the matrix elements of the operator $K_1 K_1^*$ are given by

$$K_1 K_1^*(\mathbf{q}_1, \mathbf{q}_2; \mathbf{q}_1', \mathbf{q}_2') = \int d^2 Q \delta(\mathbf{Q} - \mathbf{q}_1 - \mathbf{q}_2) \delta(\mathbf{Q} - \mathbf{q}_1' - \mathbf{q}_2')$$

$$\times M \left( \frac{1}{2}(\mathbf{q}_1 - \mathbf{q}_2), \frac{1}{2}(\mathbf{q}_1' - \mathbf{q}_2'); \mathbf{Q} \right) ,$$ \hspace{1cm} (49)
where

\[ M(\mathbf{P}, \mathbf{P}'; \mathbf{Q}) = (2\pi)^2 \int_0^L dz \kappa(Q/2 + \mathbf{P}, Q/2 - \mathbf{P}; z) \kappa^*(Q/2 + \mathbf{P}', Q/2 - \mathbf{P}'; z) . \] (50)

To find the singular functions \( g_\sigma \), we make the ansatz

\[ g_{QQ}(\mathbf{q}_1, \mathbf{q}_2) = \int d^2 P C_{Q'}(\mathbf{P}; \mathbf{Q}) \delta(\mathbf{q}_1 - Q/2 - \mathbf{P}) \delta(\mathbf{q}_2 - Q/2 + \mathbf{P}) , \] (51)

where \( \mathbf{Q} \) and \( \mathbf{Q}' \) are two-dimensional wavevectors. Eq. (43) now implies that

\[ \int d^2 P' M(\mathbf{P}, \mathbf{P}'; \mathbf{Q}) C_{Q'}(\mathbf{P}'; \mathbf{Q}) = \sigma_{QQ'}^2 C_{Q'}(\mathbf{P}; \mathbf{Q}) , \] (52)

that is \( C_{Q'}(\mathbf{P}; \mathbf{Q}) \) is an eigenfunction of \( M(\mathbf{P}, \mathbf{P}'; \mathbf{Q}) \) labeled by \( \mathbf{Q}' \) with eigenvalue \( \sigma_{QQ'}^2 \).

Note that since \( M(\mathbf{Q}) \) is self-adjoint, the \( C_{Q'}(\mathbf{P}; \mathbf{Q}) \) may be taken to be orthonormal. The singular functions \( f_{QQ'} \) may be found from (45) by direct calculation:

\[ f_{QQ}(\mathbf{r}) = \frac{1}{\sigma_{QQ'}} \int d^2 P \exp(-i\mathbf{Q} \cdot \mathbf{\rho}) \kappa^*(Q/2 + \mathbf{P}, Q/2 - \mathbf{P}; z) C_{Q'}(\mathbf{P}; \mathbf{Q}) . \] (53)

It follows that the SVD of \( K_1^+ \) is given by the expression

\[ K_1^+(\mathbf{r}; \mathbf{q}_1, \mathbf{q}_2) = \int d^2 Q d^2 Q' \frac{1}{\sigma_{QQ'}} f_{QQ}(\mathbf{r}) g_{QQ}^*(\mathbf{q}_1, \mathbf{q}_2) . \] (54)

The above expression for the SVD of \( K_1^+ \) may be simplified by using the spectral decomposition

\[ M^{-1}(\mathbf{P}, \mathbf{P}'; \mathbf{Q}) = \int d^2 Q' \frac{1}{\sigma_{QQ'}} C_{Q'}(\mathbf{P}; \mathbf{Q}) C_{Q'}^*(\mathbf{P}'; \mathbf{Q}) \] (55)

and the explicit expressions for the singular functions. Eq. (54) thus becomes

\[ K_1^+(\mathbf{r}; \mathbf{q}_1, \mathbf{q}_2) = \int d^2 Q d^2 P d^2 P' \exp(-i\mathbf{Q} \cdot \mathbf{\rho}) M^{-1}(\mathbf{P}, \mathbf{P}'; \mathbf{Q}) \times \kappa^*(Q/2 + \mathbf{P}, Q/2 - \mathbf{P}; z) \delta(\mathbf{q}_1 - Q/2 - \mathbf{P}) \delta(\mathbf{q}_2 - Q/2 + \mathbf{P}) . \] (56)

Using this result, along with (37), we obtain \( \eta^{(1)}(\mathbf{r}) \), the solution to the linearized ISP:

\[ \eta^{(1)}(\mathbf{r}) = \int d^2 Q d^2 P d^2 P' \exp(-i\mathbf{Q} \cdot \mathbf{\rho}) M^{-1}(\mathbf{P}, \mathbf{P}'; \mathbf{Q}) \times \kappa^*(Q/2 + \mathbf{P}, Q/2 - \mathbf{P}; z) \phi(Q/2 + \mathbf{P}, Q/2 - \mathbf{P}) . \] (57)

Note that the above inversion formula agrees with the results of Ref. 10. However, the derivation in Ref. 10 is based on a direct calculation of the pseudoinverse solution rather than a construction of the SVD of the linearized forward scattering operator.
4. Numerical Results

We now illustrate the inversion formulas derived in this paper with numerical examples. We will work in the planar geometry with free boundary conditions. In addition, we assume a priori that there are no inhomogeneities in the diffusion coefficient ($\delta D = 0$). This allows the use of a single modulation frequency which we set to zero. In this case the linearized inversion formula (57) can be written in the form

$$
\delta \alpha^{(1)}(r) = \int d^2Q d^2P d^2P' \exp(-iQ \cdot \rho) M^{-1}(P, P'; Q) \times \kappa_1^*(Q/2 + P, Q/2 - P; z) \phi(Q/2 + P, Q/2 - P') ,
$$

(58)

where

$$
M(P, P'; Q) = (2\pi)^2 \int_0^L dz k_1(|Q/2 + P, Q/2 - P; z|) \kappa_1^*(Q/2 + P', Q/2 - P'; z) .
$$

(59)

In practice, this formula must be discretized. Namely, we chose the vectors $Q$ to occupy a square lattice with unit step size $\Delta q = k_1 = L^{-1}$ inside the circle $|Q| \leq 40 \Delta q$. The vectors $P, P'$ were chosen on a one-dimensional lattice coinciding with the $x$-axis; the spacing was $\Delta p = 5 \Delta q = 5L^{-1}$, and $0 \leq |P| < 40L^{-1}$. Thus a total of eight different vectors $P$ were used (including $P = 0$). Note that for numerical calculation of $M^{-1}$, the operator $M$ becomes a square matrix which can be diagonalized by the methods of linear algebra. In order to avoid numerical instability, the calculation of $M^{-1}$ must be regularized. In particular, we replace $1/\sigma$ by $R(\sigma)$ where $R$ is a suitable regularizer. The effect of regularization is to limit the contribution of small singular values to the reconstruction. The simplest way to do this is to simply cutoff all $\sigma$ below some cutoff $\sigma_c$. That is, we set

$$
R(\sigma) = \frac{1}{\sigma} \theta(\sigma - \sigma_c) ,
$$

(60)

$\theta$ denoting the usual Heavyside step function.

The forward data were calculated for a spherical absorbing inhomogeneity. The data function $\phi(q_1, q_2)$ is given in the Appendix. The diffuse wave numbers are given by $k_1^2 =$
\( \alpha_0/D_0 \) outside the sphere and \( k_2^2 = (\alpha_0 + a)/D_0 \) inside the sphere. Thus, inside the sphere we have \( \delta \alpha = a = D_0(k_2^2 - k_1^2) \) and we have chosen \( D_0 = 1, \ k_1 = L^{-1} \). Reconstructions were carried out in the volume \(-L \leq x, y \leq L, \ 0 < z < L\) with the center of absorbing sphere placed at the point \((0, 0, L/2)\). The sphere’s radius was taken to be \( R = 0.4L \) and the corresponding size parameter of the sphere was \( k_1R = 0.4 \).

The results of linear reconstruction \((\delta \alpha^{(1)})\) are shown in Fig. 1. In the case \( k_1 = 0.99k_2 \), the weak scattering approximation is quite accurate. As a result, the quality of reconstructed images is high even to lowest order in \( \delta \alpha \). As the mismatch of the absorption inside and outside the sphere becomes larger, the quality of the linearized inversion decreases. In particular, a false dark area in the center of the sphere develops. In the case \( k_1 = 0.5k_2 \) \((\delta \alpha/\alpha_0 = 3)\) only a thin outer shell is reconstructed, while the inside area of the sphere is almost completely black. This is explained by the fact that in the weak scattering approximation the inhomogeneities are probed by the unperturbed incident field. However, the field inside more absorbing areas, such as the absorbing sphere in this numerical example, differs from the incident field. In essence, the field doesn’t penetrate into areas with very high absorption. The linearized reconstruction “interprets” this fact as the absence of inhomogeneity. Note that although linearized inversion is not accurate when \( \delta \alpha/\alpha_0 > 1 \), it still reconstructs the correct shape of an inhomogeneity. Thus, although the internal region of the absorbing sphere in the case \( k_1 = 0.5k_2 \) is not reconstructed, the overall spherical shape is reconstructed correctly. It is expected that this is a general property of the linearized reconstruction and is not limited to spherical shapes.

We now consider the first nonlinear correction \( \delta \alpha^{(2)} \) which is given by

\[
\delta \alpha^{(1)}(\mathbf{r}) = \int d^2Q d^2P d^2P' \exp(-i \mathbf{Q} \cdot \mathbf{\rho}) M^{-1}(\mathbf{P}, \mathbf{P'}; \mathbf{Q}) \times \kappa_1^*(\mathbf{Q}/2 + \mathbf{P}, \mathbf{Q}/2 - \mathbf{P}; z) \phi^{(1)}(\mathbf{Q}/2 + \mathbf{P}, \mathbf{Q}/2 - \mathbf{P}) ,
\]

where

\[
\phi^{(1)}(\mathbf{q_1}, \mathbf{q_2}) = \int d^8r d^8r' K_2^{11}(\mathbf{q_1}, \mathbf{q_2}; \mathbf{r}, \mathbf{r'}) \delta \alpha^{(1)}(\mathbf{r}) \delta \alpha^{(1)}(\mathbf{r'}).
\]

13
Here \( K_{2}^{11}(\mathbf{q}_1, \mathbf{q}_2; \mathbf{r}_1, \mathbf{r}_2) \) is obtained by Fourier transformation of (16):

\[
K_{2}^{11}(\mathbf{q}_1, \mathbf{q}_2; \mathbf{r}, \mathbf{r}') = \frac{G_0(\mathbf{r}, \mathbf{r}')}{(2\pi D_0)^2 Q(\mathbf{q}_1)Q(\mathbf{q}_2)} \exp \left[ i \left( \mathbf{q}_1 \cdot \mathbf{\rho}_1 + \mathbf{q}_2 \cdot \mathbf{\rho}_2 \right) \right] \\
\times \exp \left[ -Q(\mathbf{q}_1)z_1 - Q(\mathbf{q}_2)z_2 \right].
\]  

(63)

The quantity \( \phi^{(1)}(\mathbf{q}_1, \mathbf{q}_2) \) is calculated by numerical integration using the precomputed function \( \delta \alpha^{(1)} \).

The reconstructed absorption coefficient with the first nonlinear correction (\( \delta \alpha = \delta \alpha^{(1)} + \delta \alpha^{(2)} \)) is shown in Fig. 2. As can be seen by comparing the panels with \( k_1 = 0.8k_2 \) and \( k_1 = 0.9k_2 \) in Figs. 1 and 2, the effect of the first nonlinear correction is to fill in the voids that are seen in the linearized reconstruction. To illustrate this point more quantitatively, we plotted the reconstructed function \( \delta \alpha \), with and without the first nonlinear correction, as a function of the \( x \)-coordinate on the one-dimensional line determined by \( z = \text{const}, y = 0 \). The results are shown in Fig. 3. The effect of filling in the void in the center of the sphere is especially well manifested in the case \( k_1 = 0.9k_2 \).

As expected, the first nonlinear correction had no significant effect in the cases \( k_1 = 0.99k_2 \) and \( k_1 = 0.5k_2 \). In the first case, the linearized inversion already provides accurate results and all higher-order corrections are small. In the second case, the weak scattering approximation is strongly violated for the forward problem, and very high order corrections must be included to obtain convergence (provided the series converges at all).

**Appendix A: Inversion of series**

In this Appendix we show that the inverse scattering series (23) may be obtained by formal inversion of the forward scattering series

\[
\phi = K_1 \eta + K_2 \eta \otimes \eta + K_3 \eta \otimes \eta \otimes \eta + \cdots.
\]  

(A1)

To proceed, we assume that \( \eta \) may be expressed as a functional expansion in \( \phi \):

\[
\eta = K_1 \phi + K_2 \phi \otimes \phi + K_3 \phi \otimes \phi \otimes \phi + \cdots,
\]  

(A2)
where $\mathcal{K}_1$ is a linear operator which maps the Hilbert space $\mathcal{H}_2$ into the Hilbert space $\mathcal{H}_1$ and $\mathcal{K}_n$ is a tensor operator which maps $\mathcal{H}_2 \otimes \cdots \otimes \mathcal{H}_2$ ($n$ copies) into $\mathcal{H}_1$ for $n \geq 2$. To find the $\mathcal{K}$’s we substitute the expression (A1) for $\phi$ into (A2) and equate terms with the same tensor power of $\eta$. We thus obtain the relations

\begin{align}
\mathcal{K}_1 K_1 &= I \\
\mathcal{K}_2 K_1 \otimes K_1 + \mathcal{K}_1 K_2 &= 0 \\
\mathcal{K}_3 K_1 \otimes K_1 \otimes K_1 + \mathcal{K}_2 K_1 \otimes K_2 + \mathcal{K}_2 K_2 \otimes K_1 + \mathcal{K}_1 K_3 &= 0 \\
\sum_{p=1}^{n-1} \mathcal{K}_p \sum_{i_1+\cdots+i_p=n} K_{i_1} \otimes \cdots \otimes K_{i_p} + \mathcal{K}_n K_1 \otimes \cdots \otimes K_1 &= 0 ,
\end{align}

which may be solved for the $\mathcal{K}$’s with the result

\begin{align}
\mathcal{K}_1 &= K_1^+ \\
\mathcal{K}_2 &= -\mathcal{K}_1 K_2 \mathcal{K}_1 \otimes \mathcal{K}_1 \\
\mathcal{K}_3 &= - (\mathcal{K}_2 K_1 \otimes K_2 + \mathcal{K}_2 K_2 \otimes K_1 + \mathcal{K}_1 K_3) \mathcal{K}_1 \otimes \mathcal{K}_1 \otimes \mathcal{K}_1 \\
\mathcal{K}_n &= - \left( \sum_{p=1}^{n-1} \mathcal{K}_p \sum_{i_1+\cdots+i_p=n} K_{i_1} \otimes \cdots \otimes K_{i_p} \right) \mathcal{K}_1 \otimes \cdots \otimes \mathcal{K}_1 .
\end{align}

It can be seen that the above expressions for $\mathcal{K}_1$ and $\mathcal{K}_2$ agree with (23). In addition, (A10) provides a general formula for the coefficients of the higher order terms in (23). We note this formula implies that the nonlinear correction of order $n$ involves all forward operators up to order $n$.

**Appendix B: The data function for a spherical inhomogeneity**

In this Appendix we calculate the data function for an absorbing spherical inhomogeneity in an infinite medium. Note that the scattering of diffusing waves from a sphere is analogous to Mie scattering in electromagnetic theory$^{11}$.

Consider a spherical inclusion whose properties differ from the surrounding homogeneous background. We assume that $\delta D = 0$ and $\delta a = a = \text{const}$ inside a spherical region $|\mathbf{r} - \mathbf{r}_0| < \ldots$
$R$. We will work in a reference frame whose origin coincides with the center of the sphere, $\mathbf{r}_0$. In this case, the Green’s function can be represented as

$$G(\mathbf{r}, \mathbf{r}') = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} g_l(r, r') Y^*_m(\hat{\mathbf{r}}') Y_m(\hat{\mathbf{r}}), \quad (B1)$$

where the $Y_m$’s are spherical harmonics. If both the sources and detectors are located outside the sphere $(r, r' > R)$ then

$$g_l(r, r') = \frac{2k_1}{\pi D_0} [i_l(k_1 r_<) k_l(k_1 r_>) - F_l k_l(k_1 r) k_l(k_1 r')] , \quad (B2)$$

where $k_l(x)$ and $i_l(x)$ are the modified spherical Bessel and Hankel functions of the first kind, $r_<$ and $r_>$ are the lesser and greater of $r$ and $r'$, the Mie coefficient $F_l$ is given by

$$F_l = \frac{k_2 i_l(k_1 R) i_l' (k_2 R) - k_1 i_l(k_2 R) i_l'(k_1 R)}{k_2 i_l'(k_2 R) k_l'(k_1 R) - k_1 i_l(k_2 R) k_l'(k_1 R)} , \quad (B3)$$

and $k_1$ and $k_2$ are the wavenumbers outside and inside the sphere:

$$k_1^2 = \frac{\alpha_0 - i \omega}{D_0}, \quad k_2^2 = \frac{\alpha_0 + a - i \omega}{D_0}. \quad (B4)$$

By observing that in an infinite medium the unperturbed Green’s function $G_0(r, r')$ can be written as

$$G_0(\mathbf{r}, \mathbf{r}') = \frac{2k_1}{\pi D_0} \sum_{l=0}^{\infty} \sum_{m=-l}^{l} i_l(k_1 r_<) k_l(k_1 r_>) Y^*_m(\hat{\mathbf{r}}') Y_m(\hat{\mathbf{r}}), \quad (B5)$$

we see that the first term in (B2) can be identified as the incident field, while the second term represents the scattered field. Consequently, the data function $\phi(\mathbf{r}_1, \mathbf{r}_2)$ is given by

$$\phi(\mathbf{r}_1, \mathbf{r}_2) = \frac{2k_1}{\pi D_0} \sum_{l=0}^{\infty} \sum_{m=-l}^{l} F_l k_l(k_1 r_1) k_l(k_1 r_2) Y^*_m(\hat{\mathbf{r}}_2) Y_m(\hat{\mathbf{r}}_1). \quad (B6)$$

The above expression is valid in a reference frame whose origin is at the center of the sphere. The corresponding expression in an arbitrary reference frame is obtained by making the transformation $\mathbf{r}_{1,2} \rightarrow \mathbf{r}_{1,2} - \mathbf{r}_0$.

We now calculate the Fourier transformed data function $\phi(\mathbf{q}_1, \mathbf{q}_2)$ which is defined by

$$\phi(\mathbf{q}_1, \mathbf{q}_2) = \int d^2 \rho_1 d^2 \rho_2 \exp[i(\mathbf{q}_1 \cdot \mathbf{\rho}_1 + \mathbf{q}_2 \cdot \mathbf{\rho}_2)] \phi(\mathbf{\rho}_1, z_1, \mathbf{\rho}_2, z_2). \quad (B7)$$
We will show that

\[
\phi(q_1, q_2) = \frac{\pi^2}{2D_0 k_1 Q(q_1) Q(q_2)} \exp \left[ i (q_2 - q_1) \cdot \rho_c - Q(q_1) |z_0 - z_1| - Q(q_2) |z_2 - z_0| \right] \\
\times \sum_{l=0}^{\infty} (2l + 1) F_l P_l \left( \frac{q_1 \cdot q_2 + \gamma(z_1, z_2) Q(q_1) Q(q_2)}{k_1^2} \right),
\]

(B8)

where \( P_l(x) \) are the Legendre polynomials and

\[
\gamma(z_1, z_2) = \begin{cases} 
1, & \text{if } z_1 = z_2 \\
-1, & \text{if } z_1 \neq z_2.
\end{cases}
\]

(B9)

Note that the arguments of the Legendre polynomials in (B8) can be greater than unity; however the Mie coefficients \( F_l \) decay with \( l \) faster than exponentially so that the convergence of the series is guaranteed. To derive (B8) we start by expanding \( \phi(r_1, r_2) \) in a three-dimensional Fourier integral. To this end we define \( I_{l_1 m_1}^1(p_1) \) and \( I_{l_1 m_1}^2(p_2) \) such that

\[
k_l(k_1 r_1) Y_{l_1 m}(\hat{r}_1) = \int \frac{d^3 p_1}{(2\pi)^3} I_{l_1 m}^1(p_1) \exp(-i p_1 \cdot r_1),
\]

(B10)

\[
k_l(k_1 r_2) Y_{l_1}^*(\hat{r}_2) = \int \frac{d^3 p_2}{(2\pi)^3} I_{l_1 m}^2(p_2) \exp(-i p_2 \cdot r_2),
\]

(B11)

\[
I_{l_1 m}^1(p_1) = \int k_l(k_1 r) Y_{l_1 m}(\hat{r}) \exp(i p_1 \cdot r) d^3 r,
\]

(B12)

\[
I_{l_1 m}^2(p_2) = \int k_l(k_1 r) Y_{l_1}^*(\hat{r}) \exp(i p_2 \cdot r) d^3 r.
\]

(B13)

The integrals (B12) and (B13) are evaluated by using the identity

\[
\exp(i p \cdot r) = 4\pi \sum_{l=0}^{\infty} \sum_{m=-l}^{l} i^l j_l(pr) Y_{l_1}^*(\hat{p}) Y_{l_1 m}(\hat{r}),
\]

(B14)

where \( j_l(x) \) are spherical Bessel functions of the first kind. After expanding the exponents in (B12) and (B13) according to (B14) and integrating over the angular variables we obtain

\[
I_{l_1 m}^1(p_1) = 4\pi i^l Y_{l_1 m}(\hat{p}_1) \int_0^\infty r^2 k_l(k_1 r) j_l(p_1 r) dr,
\]

(B15)

\[
I_{l_1 m}^2(p_2) = 4\pi i^l Y_{l_1}^*(\hat{p}_2) \int_0^\infty r^2 k_l(k_1 r) j_l(p_2 r) dr.
\]

(B16)

The one-dimensional integrals are easily calculated using the formula

\[
\int_0^\infty x^2 k_l(ax) j_l(bx) dx = \frac{\pi}{2a} \left( \frac{b}{a^2 + b^2} \right)^l.
\]

(B17)
Combining the above results, we can write the three-dimensional Fourier expansion of \( \phi(\mathbf{r}_1, \mathbf{r}_2) \):

\[
\phi(\mathbf{r}_1, \mathbf{r}_2) = \frac{1}{(2\pi)^3 D_0 k_1} \sum_{lm} (-1)^l F_l \int d^3 p_1 d^3 p_2 \frac{(p_1 p_2 / k_1^2)^l}{(p_1^2 + k_1^2)(p_2^2 + k_1^2)} \times Y_{lm}^*(\hat{\mathbf{p}}_1) Y_{lm}(\hat{\mathbf{p}}_2) \exp \left[ -i \left( \mathbf{p}_1 \cdot (\mathbf{r}_1 - \mathbf{r}_0) + \mathbf{p}_2 \cdot (\mathbf{r}_2 - \mathbf{r}_0) \right) \right] ,
\]  

(B18)

where we have made the shift \( \mathbf{r}_{1,2} \rightarrow \mathbf{r}_{1,2} - \mathbf{r}_0 \). Thus the expression (B18) is valid in an arbitrary reference frame.

Next we decompose the three-dimensional vectors as \( \mathbf{p}_1 = -\mathbf{q}_1 + t_1 \hat{\mathbf{e}}_z \), \( \mathbf{p}_2 = \mathbf{q}_2 + t_2 \hat{\mathbf{e}}_z \) and \( \mathbf{r}_0 = \mathbf{\rho}_0 + z_0 \hat{\mathbf{e}}_z \). Taking into account that \( p_{1,2}^2 = q_{1,2}^2 + t_{1,2}^2 \), this immediately leads to the following expression for the two-dimensional Fourier transform of \( \phi(\mathbf{r}_1, \mathbf{r}_2) \):

\[
\phi(\mathbf{q}_1, \mathbf{q}_2) = \frac{2\pi \exp \left[ i (\mathbf{q}_1 + \mathbf{q}_2) \cdot \mathbf{\rho}_0 \right]}{D_0 k_1} \sum_{lm} (-1)^l F_l J^1_{lm}(\mathbf{q}_1) J^2_{lm}(\mathbf{q}_2) ,
\]  

(B19)

where

\[
J^1_{lm}(\mathbf{q}_1) = \int_{-\infty}^{\infty} dt \left( \frac{\sqrt{q_1^2 + t^2 / k_1}}{q_1^2 + t^2 + k_1^2} \right)^l Y_{lm} \left( \frac{-\mathbf{q}_1 + t \hat{\mathbf{e}}_z}{\sqrt{q_1^2 + t^2}} \right) \exp \left[ i t (z_0 - z_1) \right] ,
\]  

(B20)

\[
J^2_{lm}(\mathbf{q}_2) = \int_{-\infty}^{\infty} dt \left( \frac{\sqrt{q_2^2 + t^2 / k_1}}{q_2^2 + t^2 + k_1^2} \right)^l Y_{lm}^* \left( \frac{\mathbf{q}_2 + t \hat{\mathbf{e}}_z}{\sqrt{q_2^2 + t^2}} \right) \exp \left[ i t (z_0 - z_2) \right] .
\]  

(B21)

Although the integrands in (B20) and (B21) contain square roots, they are analytic functions of \( t \). This can be seen by examining the explicit expressions for the spherical harmonics in terms of the associated Legendre polynomials and observing that the square roots in question are raised to an even power for any \( l \) and \( m \). Therefore, (B20) and (B21) can be evaluated by analytic continuation of the integrands into the complex plane and contour integration.

The result is

\[
J^1_{lm}(\mathbf{q}_1) = \frac{\pi i^l}{Q(\mathbf{q}_1)} Y_{lm} \left( \frac{-\mathbf{q}_1 + i \text{sgn}(z_0 - z_1) Q(\mathbf{q}_1) \hat{\mathbf{e}}_z}{ik_1} \right) \exp \left[ -Q(\mathbf{q}_1) |z_0 - z_1| \right] ,
\]  

(B22)

\[
J^2_{lm}(\mathbf{q}_2) = \frac{\pi i^l}{Q(\mathbf{q}_1)} Y_{lm}^* \left( \frac{\mathbf{q}_2 + i \text{sgn}(z_0 - z_2) Q(\mathbf{q}_2) \hat{\mathbf{e}}_z}{ik_1} \right) \exp \left[ -Q(\mathbf{q}_2) |z_0 - z_2| \right] .
\]  

(B23)
Note that the spherical harmonic functions in the above expressions are analytically continued to complex angles; the arguments of $Y_{lm}$ in (B22) and (B23) are complex unit vectors with the property $\mathbf{a} \cdot \mathbf{a} = 1$.

Finally, we use the addition theorem to perform the summation over the index $m$ in (B19):

$$
\sum_{m=-l}^{l} Y_{lm} \left( \frac{-q_1 + i \text{sgn}(z_0 - z_1)Q(q_1)\hat{e}_z}{ik_1} \right) Y_{lm}^* \left( \frac{q_2 + i \text{sgn}(z_0 - z_2)Q(q_2)\hat{e}_z}{ik_1} \right) = \frac{2l + 1}{4\pi} P_l(\cos \theta),
$$

(B24)

where $\theta$ is the angle between the two complex vector arguments of the spherical harmonic functions in (B24). The cosine of this angle is obviously given by

$$
\cos \theta = \frac{\mathbf{q}_1 \cdot \mathbf{q}_2 + \text{sgn}(z_0 - z_1)\text{sgn}(z_0 - z_2)Q(q_1)Q(q_2)}{k_1^2}.
$$

(B25)

Taking into account that $\text{sgn}(z_0 - z_1)\text{sgn}(z_0 - z_2) = \gamma(z_1, z_2)$, we obtain the result (B8).
